

Lines Through Meteorite Craters to Visoko

By: Mika Virpiranta, Mr. Sc., Finland,
mika.virpiranta@hotmail.com

My primary source for meteorite craters was *Expert Database on Earth Impact Structures (EDEIS)* of Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Tsunami Laboratory, Novosibirsk, Russia. I consider, from user experience, EDEIS as most reliable of all sources available in meteorite crater data.

EDEIS lists 1140 astrobleme, comet, and meteorite impact structures.

Meteorite crater application in Google Earth was used, also. However, it is quite unreliable and its location markings needs close re-verification almost in all cases. Still, using Google Earth's own locations gave some shortcuts over otherwise arduous manual work.

Meteorite craters are marked in Google Earth with colour code: Red for discredited, blue for suspected, with white for considered, and purple for fully confirmed. All these four type craters were accepted into analysis, because almost all of discredited red craters are volcanic ones, and hypothesis set in "Straight Lines through Volcanoes to Sun Shrines" says that thunder gods ruled volcanoes and meteorites are hammers of thunder gods: this interpretation equals volcano craters with meteorite craters as both are phenomenon ruled by will of thunder gods. And geological fact is that meteorite strike creates volcano-like eruption, albeit very short-living

one, if compared to real volcanoes which can erupt millions of years like Hawaii has done.

Research method was simple: origin point of Google Earth ruler was put onto meteorite crater as far away from Visoko as possible and then draw the yellow line onto top of Visoko, using round tower structure of Old Visoko as an insertion point.

If there was minimum one other meteorite crater on the same yellow laser straight line, then I accepted this line as a meteorite line.

Marginal was outermost known rim of a meteorite crater. If yellow line run outside of this rim of a meteorite crater this crater was not accepted into the line although the crater could become accepted into another line.

This is method everybody can duplicate and thus verify very easily: open your computer, activate Google Earth Meteorite Database, set your target, start drawing lines into that target, and see what lines run through craters.

Lines through all craters were not analyzed. Thus there might be (and almost certainly is) more lines to Visoko than listed here. Still, 281 lines is enormous number as every line runs through *at least* two craters, and in several cases through six or seven craters per same one line.

By chance there should not occur even one such line, and—in fact—if the point of insertion is moved few kilometres somewhere else then none occurs. This was tested also.

Thus result of analysis is that location of Visoko was chosen because Visoko creates maximum amount of ostensible

straight lines through maximum amount of meteorite craters per line.
